

Dynamic Volumetric Imaging with the FV3000RS Confocal Microscope: 3D Reconstruction of Actin Dynamics in a *Colletotrichum graminicola* Spore

Colletotrichum graminicola is a widespread fungal pathogen and a major disease-causing agent of cereal crops, including wheat and corn. In corn, fungal infections of *C. graminicola* cause anthracnose leaf blight, resulting in severe crop damage and major economic losses for farmers. Understanding the cytoskeletal dynamics in germinating *C. graminicola* spores could therefore contribute to the prevention of disease.

Pregermination Organization of Filamentous Actin Cables

In this experiment, the FLUOVIEW FV3000RS microscope was used to study the actin dynamics of a *C. graminicola* spore prior to germination. Filamentous actin cables can be observed within a crescent-shaped spore that has yet to germinate. The cables have organized to extend lengthwise across the spore at the plane of contact with the surface. The actin cables can be seen retracting from the center towards either end of the spore.

Figure 1. XYZT reconstruction of actin dynamics in a spore of *C. graminicola* before germination.

Imaging conditions

Objective: 100X oil 1.49NA TIRF objective (UAPON100XOTIRF)

Microscope: FLUOVIEW FV3000RS laser scanning confocal microscope

Lasers: 488 nm (GFP, green), 561 nm (DIC, gray)

Scanner: Resonant scanner

XY frames: 0.272 sec/frame

Z series: 22 steps (6 sec/section)

T series: 30 Z stacks acquired over 3 minutes

Observation of Two Distinct Cytoskeletal Events during Germination

Following the organization of actin into cables, the germination process of a *C. graminicola* spore is marked by two successive cytoskeletal events, with the formation of both patches and cables during both events. In the first event, the cytoskeleton rearranges to form a septum that delineates the fungal spore into two distinct cells (depicted by the medial barrier across the width of the spore). Following the septation event, actin cables form at the site of germination and extend into the developing germ tube toward the apex. These two events can be seen in Figures 2 and 3.

[Maintaining Focus during 4-Dimensional Time-Lapses with Olympus' TruFocus Z-Drift Compensation System](#)

[Rapid Four-Dimensional Acquisition with the Resonant Scanner](#)

The FV3000RS microscope features a high-performance resonant scanner that enables rapid acquisition time-lapses of live-cell dynamics. The resonant scanner in the FV3000RS microscope also maintains a full 1X field of view with FN 18, with imaging speeds of 30 frames per second at 512 × 512 pixels. Using the resonant scanner, researchers can acquire Z stacks of numerous planes in seconds, achieving high-resolution Z stacks of rapidly occurring phenomena in live cells.

[TruSpectral GaAsP Detectors Provide High Sensitivity for Live Cell Imaging](#)

Integrated in all FV3000 confocal microscopes, TruSpectral detection technology enables higher light throughput compared to conventional spectral detection units. The volume phase hologram diffracts light with an up to three-fold higher transmission efficiency than reflection gratings. When combined with high-efficiency GaAsP PMTs, the FV3000 microscope's high-sensitivity spectral detector (HSD) requires minimal laser power to obtain high signal-to-noise images, enabling powerful yet gentle live cell imaging.

Comment by Joseph Vasselli and Dr. Brian Shaw

Our research has the goal of understanding the role of the cytoskeleton and endocytic proteins in growth and development in filamentous fungi. Tracking the spatiotemporal localization of these proteins during shifts in growth polarity is crucial to our experiments. The FV3000 microscope's superb Z-drift compensation, high-sensitivity detectors, and rapid resonant scanner enables us to acquire high-resolution XYZTs to effectively interrogate the dynamics of these proteins in live cells.

激光扫描共焦显微镜

FV4000

- 改变了游戏规则的大动态范围，实现从宏观尺度到亚细胞结构的成像
- 采用TruSpectral技术可扩展多达6个通道的同步多色成像能力
- 重新设计的高速、高分辨率扫描单元，可进行固定细胞和活细胞的高效成像
- 凭借出色的近红外（NIR）功能和高品质光学器件，提供优异的成像深度和灵敏度
- 可靠、可重复的SiIVIR探测器让研究者安枕无忧
- 业界出色的*10条激光谱线，提供从405 nm到785 nm的更广光谱范围

*截至2023年10月。

用于超高分辨率成像或全内反射成像的高分辨率物镜

APON-TIRF/UAPON-TIRF/UPLAPO-HR

这些复消色差物镜具有较高的数值孔径值，针对高对比度全内反射荧光和超分辨率成像进行了优化。通过UPLAPO-HR物镜的高NA实现宽平面度，可实现对活细胞和微细胞器的实时超分辨率成像。

- 高NA可形成适用于高对比度全内反射荧光图像或超分辨率的倏逝波场
- HR系列是世界上较早*推出的第一个可实现宽平面度的NA1.5平面复消色差物镜

*截至2018年11月。根据奥林巴斯的调查结果。
